## Introduction

The Model 42 is designed to create broadcast-standard IFB circuits from line-level audio sources. The unit's primary application is to interface analog outputs associated with digital matrix intercom systems with broadcast IFB user devices. The Model 42 provides four independent IFB circuits. Each IFB circuit provides DC power and two analog audio signals to support the connected IFB user devices. The Model 42's audio quality is excellent; little hiss, hum, or other artifacts are present. Installation is very simple. Audio input connections are made using a 25-pin D-subminiature connector. The IFB output circuits interface using standard 3-pin XLR-type connectors. The compact, one-rack-space package is constructed using heavy-gauge steel components. The unit's mains power input can range from 100 to 230 volts, 50/60 hertz. This "universal input" ensures correct operation virtually anywhere in the world.

There may be persons not familiar with the term IFB. That's not unreasonable as it's a somewhat obscure acronym for interrupted foldback. (It can also be known as interruptible foldback.) On its own, the term foldback is an alternate way of describing a cue or monitor function. Adding "interrupted" before it means that the cue source can be temporarily replaced with an audio signal originating from a producer, director, or other production personnel. IFB circuits are often used in the broadcast industry for talent cueing applications, both in studio and field settings. Both "dry" and "wet" IFB circuits can be deployed and their characteristics are worth reviewing. The term "dry" IFB typically refers to a transformer-balanced line-level audio circuit with a +4dBu nominal level. This is essentially a standard audio circuit that is commonly used to interconnect audio equipment. The term "wet" IFB refers to a circuit that combines DC power and one or two channels of analog audio. The audio is unbalanced with a typical nominal level of -10dBu. A

Audio input connections

wet IFB circuit is the type implemented by the Model 42. As such, in this user guide the term IFB will always represent this type of circuit.

IFB circuits provide an effective means of delivering power and two channels of audio to user devices by means of standard audio cables. These cables, ubiquitous to the audio industry, interface using 3-pin male and female XLR-type connectors. With IFB circuits and standard audio cables it's a simple matter to support user devices such as listen-only belt packs and announcer's consoles with no external power source required. Whether 100 or 1000 feet apart, reliable operation can be provided.

In many cases, the Model 42 Interface will be used in on-air television applications. Whether installed in a fixed location or as part of a remote facility, excellent performance can be obtained. In addition, the Model 42 is applicable for non-broadcast applications. For example, audio recording and post-production facilities can also effectively use the unit. Combined with stereo or mono listen-only belt packs, also available from Studio Technologies, a variety of headphone cue systems can easily be deployed. As the Model 42's audio inputs are compatible with standard line-level audio signals virtually any analog source can be connected.

## **Four Independent IFB Circuits**

The Model 42 supplies four independent IFB circuits. Each circuit consists of two audio inputs and a "wet" IFB output circuit. The audio inputs are transformer coupled, have a nominal level of +4dBu, and are compatible with balanced or unbalanced sources. In on-air television broadcast

applications the audio sources will often be analog outputs from matrix intercom systems. Two sources are typically designated to feed user cue signals to stereo or monaural headsets or headphones. Generally one source is configured in the matrix intercom system as "interrupt" while the other is configured as "program." An alternate term often used for the "interrupt" channel is "program-with-interrupt." This may be more descriptive as the function is actually a program source that gets interrupted with talkback audio. The "program" channel is typically a continuous source of program audio. An alternate term is "program-only." For other applications, the Model 42's audio inputs can be connected to a 2-channel or stereo audio source. This configuration may prove useful in radio broadcasting, audio-with-picture, or recording studio applications.

Maintaining excellent audio performance was a major Model 42 design goal—the hiss, hum, and noise associated with typical IFB circuits was simply not acceptable. The Model 42 meets those requirements with audio that is "on-air" quality: low distortion, high signal-to-noise ratio, and ample headroom. On-air talent and guests, production personnel, and technicians will all appreciate the clean, quiet cue signal.

The Model 42's IFB circuits provide DC power and two channels of unbalanced audio over a single 3-conductor output. The DC output is nominally 30 volts with a maximum rated current of 200 milliamperes. A major strength of the Model 42 is the IFB circuit's ability to effectively deliver DC power over a variety of conditions. Unlike other interface devices that use a common but less-than-ideal

circuit topology, a unique IFB circuit was developed by Studio Technologies to achieve the desired performance goals. The result is a major improvement in effectively supporting IFB user devices over a wide range of conditions. Connected devices can draw up to the full rated 200 milliamperes of current with little drop in DC voltage. This output voltage stability is the key—whether drawing 50, 100, or 200 milliamperes, the output will remain close to 30 volts. In practical terms this means that reliable IFB-based cue systems can now be deployed in more stadiums, concert halls, or motor racing facilities than was previously possible; longer cable runs, more user devices, excellent performance.

## Compatibility

The Model 42 is compatible with virtually every digital matrix intercom system, including those from Clear-Com®, Drake, RTS™, and Riedel Communications. Interfacing requires only the connection of analog output ports from the intercom system to the Model 42's audio inputs. With the Model 42's excellent audio and power delivery performance it's an ideal alternative to the interface devices offered by the intercom system vendors. Using the Model 42 the intercom system's audio quality can be maintained all the way to the IFB users.

The Model 42's IFB circuits allow virtually every IFB user device to be supported. These include the Model 30-series listen-only belt packs and Model 200-series announcer console products from Studio Technologies. The 200-series units combine a variety of microphone control, headphone monitoring, IFB and intercom

system interfacing, and related functions into compact desktop units. Industry-standard listen-only belt packs from RTS, including the 4020 and 4030, can also be directly supported.

## Alternate Applications

In addition to broadcast intercom applications, the Model 42 can be used to create high-performance stereo headphone cue systems. Stereo line-level signals coming from audio consoles, routing switchers, or off-air receivers can be connected to the Model 42's audio inputs. The IFB circuits can be connected to listen-only belt packs, several models of which are available from Studio Technologies. For example, the Model 35 Talent Amplifier will allow one or two pairs of stereo headphones to be supported. Each of the four Model 42 IFB circuits will support up to six Model 35 Talent Amplifiers.

## Installation

In this section you will be installing and interconnecting the Model 42. The one-rack-space unit will be mounted in an equipment rack. Audio input connections will be made by way of a 25-pin D-sub-miniature connector. IFB circuits will be interfaced using four 3-pin XLR-type connectors. AC mains power is connected by means of a detachable cord set that is compatible with the Model 42's 3-pin IEC 320 C14-type inlet connector.

## System Components

The shipping carton contains the Model 42 Interface and associated user guide. Units destined for North America and Japan also include an AC mains cord. Your

dealer or distributor should provide an AC mains cord for other destinations.

## Locating the Model 42

The Model 42's IFB circuits provide DC power and unbalanced audio to operate external IFB user devices. These devices are often IFB "belt packs," broadcast announcer consoles, or other "talkback boxes." The Model 42's mounting location will dictate the length of the cable runs needed to link the unit with the connected devices. In some cases the location choice is already established. For example, in field broadcast applications the Model 42 will almost always be located in a production truck or trailer. But in fixed applications it may be possible to select the Model 42's mounting location so as to minimize cable length. In general, shorter cables will lead to more reliable and consistent system performance.

## Mounting the Model 42

Once the desired mounting location has been selected, the Model 42 will require one space (1.75 vertical inches) in a standard 19-inch (48.3cm) equipment rack. Secure the unit into the equipment rack using two mounting screws per side.

## Audio Input Connections

The Model 42 has eight line-level audio inputs, arranged as four 2-channel pairs. Each pair serves one of the four IFB circuits. Each IFB circuit, along with its two associated audio inputs, is completely independent. For on-air television applications the IFB sources are generally configured to provide a single- or dual-channel cue "feed" to talent personnel. In such cases channel one of a pair is generally designated as the "interrupt" channel

while channel two is the "program" channel. For other broadcast applications, such as live radio, it's possible that a stereo cue source will be connected. In this situation the left source would be connected to input channel one while the right source would be connected to input channel two. This might also be the case with other professional audio applications, such as recording and post-production.

Audio input connections are made by way of one female 25-pin D-subminiature connector which is located on the Model 42's back panel. A cable harness is required with a 25-pin D-sub plug (male) on one end and the desired mating connectors on the other. This cable harness is not supplied by Studio Technologies. (Note that in some locations the term "cable loom" may be used instead of "cable harness.") The wiring scheme used by the D-sub complies with the now-ubiquitous one made familiar by TASCAM® with their DA-88® product. A wiring harness prepared for connection to the Model 42's audio inputs is identical to a DA-88-style input harness. Please refer to Figures 1 and 2 for connection details. Note that unlike a DA-88-style harness, the Model 42's D-sub connector's hold-down screws use 4-40 threads. This complies with the original design standard for D-subminiature connectors which used English rather than metric thread pitch.

The Model 42's audio input circuits have a nominal signal level of +4dBu. They are transformer coupled, have a nominal impedance of 10K ohms, and compatible with balanced or unbalanced sources. Balanced sources should be wired so that signal high is connected to the + pins, signal low to the - pins, and shield to the shield pins. With unbalanced sources,

Connections	Signal High (+)	Signal Low (-)	Shield
IFB Circuit 1-Interrupt	24	12	25
IFB Circuit 1-Program	10	23	11
IFB Circuit 2-Interrupt	21	9	22
IFB Circuit 2-Program	7	20	8
IFB Circuit 3-Interrupt	18	6	19
IFB Circuit 3-Program	4	17	5
IFB Circuit 4-Interrupt	15	3	16
IFB Circuit 4-Program	1	14	2

- Notes:** 1) Connector type on Model 42 is 25-pin D-subminiature female. Installer must provide plug (male). Connector uses 4-40 threaded inserts for locking with mating plug.
- 2) Wiring scheme follows TASCAM DA-88 convention. Standard DA-88-type wiring harnesses are directly compatible, with the exception of 4-40 screw threads being required.

---

**Figure 1. Connections for Audio Inputs using IFB Nomenclature**

---

Connections	Signal High (+)	Signal Low (-)	Shield
IFB Circuit 1-Channel 1	24	12	25
IFB Circuit 1-Channel 2	10	23	11
IFB Circuit 2-Channel 1	21	9	22
IFB Circuit 2-Channel 2	7	20	8
IFB Circuit 3-Channel 1	18	6	19
IFB Circuit 3-Channel 2	4	17	5
IFB Circuit 4-Channel 1	15	3	16
IFB Circuit 4-Channel 2	1	14	2

- Notes:** 1) Connector type on Model 42 is 25-pin D-subminiature female. Installer must provide plug (male). Connector uses 4-40 threaded inserts for locking with mating plug.
- 2) Wiring scheme follows TASCAM DA-88 convention. Standard DA-88-type wiring harnesses are directly compatible, with the exception of 4-40 screw threads being required.

---

**Figure 2. Connections for Audio Inputs using Dual-Channel Nomenclature**

---

connect signal high to the + pins, and shield to both the – and the shield pins. If connecting an unbalanced source in this manner results in hum or noise, try connecting signal high to the + pins, and shield to the – pins; leave the shield pins unterminated.

As previously mentioned, the Model 42 is compatible with matrix intercom systems from Riedel Communications. Appendix A, located near the end of this user guide, provides detailed connection information.

## Audio Input Source Level Adjustment

Literally any audio source with a nominal operating level of +4dBu can be successfully connected to the Model 42's audio inputs. Transformer coupled, the inputs are compatible with balanced or unbalanced signals. In many applications the analog outputs from digital matrix intercom systems will be connected to the Model 42. It's important to confirm and, if required, adjust the nominal output level provided by the specific system. In reality, a nominal level that deviates somewhat from exactly +4dBu is acceptable. But with the power of contemporary computer-controlled intercom systems, there's no reason why a precisely calibrated system can't be easily implemented.

From our research we found that the Clear-Com Eclipse™ system specifies a nominal level of 0dBu. Since their headroom is listed as greater than 18dB, increasing the nominal level of their analog output ports by 4dB (to achieve the desired +4dBu) should be acceptable. RTS in their ADAM™ and ZEUS™ systems specify nominal output levels of +8dBu.

With these systems maximum Model 42 performance would be provided by reducing their nominal output levels by 4dB. With the Artist™ system from Riedel, the analog ports have a nominal level of +6dBu. A 2dB reduction in their output level would be beneficial.

### **IFB Circuits**

As mentioned previously, the Model 42 has four independent IFB output circuits each supplying DC power and two channels of unbalanced audio. The IFB circuits are designed to connect to a variety of devices that conform to the broadcast IFB standard. In this implementation pin 1 is used for a combination of shield, DC power return, and audio common; pin 2 supplies a combination of DC power and one channel of unbalanced audio; pin 3 supplies a second channel of unbalanced audio. The DC power supplied on pin 2 is 30 volts nominal with a maximum current of nominally 200 milliamperes. The audio superimposed on the DC power has a nominal signal level of -10dBu. Its audio source is the channel one audio input associated with that specific IFB circuit. The audio on pin 3 also has a nominal signal level of -10dBu. Its audio source is the channel two audio input channel associated with that specific IFB circuit.

The Model 42's IFB circuits are interfaced using four 3-pin male XLR-type connectors which are located on the unit's back panel. The associated interface cables, one for each IFB circuit, must be terminated with 3-pin female XLR-type connectors. In most cases the IFB circuits should be wired by way of an input/output connector panel rather than directly to the external devices. It's also recommended that the panel have

“mults” (multiple connectors) for each of the IFB circuits. For troubleshooting purposes it also may be useful to have the IFB circuits pass through points on an audio patch bay.

The type of interconnecting cable used between the Model 42's IFB circuits and the user devices will vary by application. In a fixed installation it would be typical to use 22AWG, shielded, stranded cable in either a single- or 2-pair configuration. With single-pair cable, pin 1 should be connected to shield. Pins 2 and 3 would connect to the cable pair.

If 2-pair cable is used, pin 1 should connect to one side of each pair, with pin 2 going to one side of pair one and pin 3 going to one side of pair two. The shields can either go only to the XLR connector shells, or to both the connector shells and pin 1. Shielding unbalanced audio signals can be a tricky proposition. It is recommended that the focus be on using excellent twisted-pair cable, rather than worrying about whether or not it is shielded. The typical foil shields used in much of the contemporary audio cable generally offers very limited effectiveness. The best rule to follow is to try to minimize exposure to large noise sources. (Okay, so that's hardly ever practical but at least it's a nice dream!)

In the event that very long cable runs are required, the resistance of the cable can impact the DC power supplied by the Model 42. There's no way to get around the fact that some DC voltage will be dropped by the interconnecting cable. A simple ohms law calculation will tell you the impact a specific cable run will have. You'll need to know the current draw of the

connected device(s), the minimum voltage required by the connected device(s), and the resistance of the cable's conductors. This is generally stated as ohms per 1000 feet. Make sure that you account for the resistance in both the pin 1 and pin 2 legs! In general, if there is the potential for a cable-length problem, moving to a more substantial cable gauge, such as 20, 18, or 16 can be effective.

## AC Mains Power

The Model 42 operates directly from AC mains power of 100 to 230V, 50/60Hz. Being a "universal input" device, there are no switches to set or jumpers to install to match a location's nominal mains voltage. For locations that have a mains power source of 240 volts, contact Studio Technologies for confirmation that a direct connection can be made.

The Model 42 uses a 3-pin IEC 320 C14-type inlet connector to mate with a detachable mains cord set. For units shipped to North America and Japan a cord is supplied that has a North-American (NEMA 15L) standard plug on one end and an IEC 320 C13-type connector on the other. Units bound for other destinations require that the appropriate cord set be obtained. The wire colors in the mains cord must conform to the internationally recognized color code and should be terminated accordingly:

<u>Connection</u>	<u>Wire Color</u>
Neutral (N)	Light Blue
Line (L)	Brown
Protective Earth (E)	Green/Yellow

**Safety Warning:** The Model 42 does not contain an AC mains disconnect switch. As such, the AC mains cord plug serves as the disconnection device. Safety considerations require that the plug and associated inlet be easily accessible to allow rapid disconnection of AC mains power should it prove necessary.

As soon as AC mains power is applied, the Model 42's power present LED will light. The unit is now fully functional.

## Operation

There are no switches, potentiometers, or user controls associated with the Model 42. It's designed for continuous operation with no adjustment or maintenance required. Proper operation will take place as long as attention is paid to the level presented on the audio inputs and the loading placed on the IFB circuits.

## Troubleshooting

If you're having trouble getting the Model 42 up and running, this section may help. If you haven't read the previous sections of this guide, you should do so before proceeding.

### If the Model 42 Doesn't Work At All

A source of AC mains power must be connected to the Model 42. The unit is a "universal input" type so that applying anything between 100 and 230 volts, 50/60Hz is acceptable. Whenever mains power is connected the front-panel

power present LED should be lit. This LED is powered by the internal 36 volt DC power supply that is used by the circuitry. If the LED is not lit confirm that AC mains power is active (“hot”) and that the cord is securely mated with the inlet connector on the Model 42’s back panel.

In all foreseeable situations, both normal and abnormal, the front-panel LED should be lit. However, it’s possible that if all four IFB circuits are being presented with a short circuit-condition, the internal 36 volt power supply may enter its protection mode and shut down. In this case the LED will not light, or will light intermittently. If the LED presents this scenario, even after confirming that mains power is correctly being applied, try removing the loads from the IFB circuits. The easiest way to do this is to remove the 3-pin female XLR-type connectors that are plugged into the Model 42’s back panel. If after a few seconds the LED again lights, carefully check the IFB circuit wiring for fault conditions.

If the LED still doesn’t light, even after confirming that mains power is present and that the IFB circuits are not shorted, it’s likely that the unit requires factory service. For safety in the event of a major internal failure, the internal 36 volt power supply contains a fuse in series with the incoming mains power. This fuse will open (“blow”) only if a serious failure occurs inside the unit. The fuse is not field-replaceable. The Model 42 must be returned to the factory, or an authorized service location, for review and repair.

## **Maintaining Correct Input Signal Levels**

The Model 42’s four 2-channel audio inputs are designed for nominal signal

levels of +4dBu. Applying signal levels significantly lower than +4dBu will reduce the signal-to-noise ratio (raising the perceived noise floor) and can prevent the connected user devices from operating optimally. Applying signal levels significantly higher than +4dBu will reduce the headroom and greatly increase the chance of reaching audio “clipping.” Obviously, these cautions are not unique to the Model 42, but apply to most audio equipment.

The easiest means of confirming that the Model 42 is being presented with the correct audio levels is to use a Model 72 Level Meter/Interface, also available from Studio Technologies. The Model 72 is a compact, portable device that plugs directly into IFB or intercom circuits and provides two useful functions. Two 5-segment LED meters display the audio levels present on pins 2 and 3 of the connected circuit. In addition, two “dry” line-level audio outputs are provided. The Model 72 should prove to be very useful, both during initial Model 42 installation and routine system testing. Complete information on the Model 72 is available on the Studio Technologies website.

## **Maintaining Correct IFB Circuit Current Draw**

Each of the four IFB circuits is designed to provide up to 200 milliamperes of DC current. By design, the IFB circuits are protected so that an overload condition, or even a complete short circuit, should not cause damage. Exceeding 200 milliamperes will cause the protection circuitry to come into play. An overload condition will cause the output voltage to shut off continually or intermittently. The exact

action will depend on the specific overload condition that is present. In general, the more extreme the overload condition, the sooner normal operation will cease. Restoring the output load to be within the rated 200 milliamperes will allow the output to again operate normally. A few seconds may be required from the time an overload condition is removed and when normal operation again takes place. Please don't test the Model 42's ability to sustain frequent overload or short-circuit conditions! The long-term reliability of the unit can be impacted by the stress caused by these fault conditions.

If there is concern that excessive loads are being placed on one or more of the IFB circuits, performing a simple test is recommended. This can be performed using any good-quality digital multimeter. Begin by setting the meter to measure DC current. Then place the meter leads in series with the pin 2 lead of the XLR-type connector associated with the IFB circuit to be tested. The easiest way to measure the pin 2 current is to create a simple adapter cable using one female and one male 3-pin XLR-type connector. Connect pin 1 on both connectors together. Connect pin 3 on both connectors together. Connect separate wires to the pin 2 leads on both connectors. Then connect the meter leads to these two wires. The meter will indicate the DC current being drawn while normal operation of the connected device(s) takes place. Be certain to connect the maximum number of devices that might be powered by the IFB circuit. That is, measure the worst-case condition and ensure that the load is within the rated 200 milliamperes output. If possible, leaving a 10 or 20% reserve margin is a good practice.

## Technical Notes

### Cable Length

There are no hard and fast rules defining the maximum cable length possible when connecting user devices to Model 42 IFB circuits. The maximum cable length is directly related to the amount of resistance in the connecting cable; the lower the resistance per foot (or meter), the longer the cable can be. (Although cable capacitance affects high-frequency performance, resistance is the limiting factor in this case.) For example, a standard 20 AWG microphone-type cable is Belden 8412, which has 10.9 ohms resistance per conductor per 1000 feet. Since we're using two conductors to carry the signal (pins 1 and 2) you'd get 21.8 ohms per 1000 feet of cable. By knowing the cable resistance value, along with the minimum voltage and maximum load current required by an IFB user device, a simple "ohms law" calculation will tell you the maximum cable length.

Let's use the example of a Studio Technologies Model 200 Announcer's Console being connected to a Model 42 IFB circuit. We'll select Belden 8412 as the interconnecting cable. For correct operation, the Model 200 needs at least 24 volts DC between pins 1 and 2 of its IFB input connector. It has a current draw of 95 milliamperes. The Model 42's IFB circuit presents an output voltage of 30 volts across pins 1 and 2 and can supply a maximum current of 200 milliamperes. (As the Model 200's current draw is well within the Model 42's capability, this is not a limiting factor.) The difference between the voltage supplied by the Model 42 (30 volts) and the voltage required by

the Model 200 (24 volts) allows a 6 volt maximum drop over the interconnecting cable. Using the current draw and maximum voltage drop figures, the maximum cable resistance can easily be calculated: 6 volts divided by 0.095 amperes equals 63 ohms. And finally, with 8412's 21.8 ohms (total) per 1000 feet of cable, a maximum of 2890 feet of cable can be used and still be less than or equal to 63 ohms. Using this example as a guide, entering the appropriate values will allow you to determine the maximum cable length for your application.

### **Cabling Issues – Crosstalk**

The Model 42's IFB circuits conform to a broadcast industry standard for sending DC power and two channels of audio over a single pair with shield audio cable. This implementation allows standard portable cables, such as are used for microphone signals, to interconnect various IFB user devices. This method is undoubtedly convenient and practical, but is not without limitations. The main audio quality issue is the possibility of crosstalk between the two audio channels. This issue arises due to the capacitance presented by the two wires that form the twisted pair. The greater the capacitance presented and the longer the cable run, the greater the crosstalk will become. Is this normally a problem during actual use? No. But it's something that should be noted.

Studio Technologies did some experimenting with various cables and the crosstalk that was created. For example, a 1000-foot reel of 24-gauge 2-pair unshielded telephone cable was used to link a Model 42 IFB circuit with an IFB user device. One pair carried the pin 2 (DC with channel 1 audio) and pin 3 (channel 2

audio) connections. While one wire from the second pair carried the pin 1 (DC and audio common) connection. The inter-channel crosstalk in the voice audio band was on the order of -45dB. Is this a good value for "professional" audio? Of course not. But for the intended talent cueing applications it should be fine. In almost all cases the audio signals being carried are somewhat or fully phase-coherent. A bit of one channel getting into the other won't even be noticed, especially since monitoring is generally done using headsets, headphones, or ear pieces.

Is it possible to reduce the crosstalk that is created? Absolutely, as long as a nonstandard cable connection is made. This becomes a trade-off between an improved crosstalk figure and ease of installation and use. Using two full pairs can significantly reduce crosstalk. Several connection schemes are possible; the exact one selected will depend on the specific installation and personal technical philosophy. Two unshielded twisted pairs can be effectively used. The first pair would carry the DC and channel 1 audio signal and common. The second pair would carry the channel 2 audio signal, again along with common. There will still be some capacitance between the conductors carrying the two audio channels but it should be significantly less. Two shielded pairs can also be used as was discussed in the Installation section of this user guide.

### **Superior Power Delivery and Audio Quality**

As previously discussed, one of the Model 42's strengths is its ability to very effectively deliver energy to the connected IFB

---

## Model 42 Interface

---

user devices. This allows more devices to be supported over longer cable runs. How does the Model 42 accomplish this? Simply by having circuitry that is superior to that used in most of the “industry-standard” equipment. In most IFB interface devices, an adjustable voltage regulator integrated circuit is used as a combination of audio modulator and current limiter. While this is a simple and inexpensive solution, it’s not without significant limitations. The major problem with this method is the type of voltage-current “knee” that is created. As the load current increases past about 50% of the rated maximum the output voltage begins to decrease. This means that the usable

power delivered to the connected device(s) will start to drop well before the rated output is reached. This limitation will become significant in applications that use long cable runs. As the IFB circuit voltage begins to drop problems with user device performance can occur. Contrast this situation with the performance provided by the Model 42. The DC voltage supplied by its IFB circuits won’t “poop out” when loaded over its 0 to 200 milli-amperes range. This will allow IFB belt pack and announcer’s console devices to work correctly in many more applications. Figure 3 shows the IFB circuit voltage-current curves for the RTS 4000-series and the Model 42 Interface. The performance differences are quite interesting.

Figure 3. IFB Circuit Voltage-Current Curves for RTS 4000-Series and Model 42 Interface

It's interesting to note the reason why typical IFB circuit audio quality is less than pristine. It's not hard to notice the background "hiss" that is always present on pin 2 (DC with channel 1 audio) of the interface connector. Technically, it's white noise that comes from the adjustable voltage regulator being used as an "AM" modulator and current limiter. The noise is an artifact of the design topology and simply can't be overcome. How does Studio Technologies know this? Because our first "breadboard" designs used this method and achieved the same poor results! Only after the problem came to light did work on an improved circuit begin. The results were worth the effort.

## Specifications

### **General Audio:**

#### **Frequency Response:**

Pin 2 Outputs (DC with Channel 1 Audio):

20Hz-20kHz  $\pm 2.5$ dB (80Hz-20kHz  $\pm 0.25$ dB)

Pin 3 Outputs (Channel 2 Audio): 20Hz-20kHz  $\pm 0.25$ dB

**Distortion (THD+N):** pin 2 outputs (DC with channel 1 audio) 0.01%, ref +4dBu in, measured at 1kHz

**S/N Ratio:** pin 2 outputs (DC with channel 1 audio) 80dB, ref +4dBu in, 20Hz-20kHz

**Crosstalk:** 81dB, typical, ref +4dBu in, 20Hz-20kHz

**Audio Inputs:** 8, organized as four 2-channel inputs

**Type:** transformer balanced, capacitor coupled, compatible with balanced or unbalanced sources

**Impedance:** 10k ohms, nominal

**Nominal Level:** +4dBu

### **IFB Circuits:** 4

**Type:** "wet" (DC power with two channels of unbalanced audio)

**Connections:** common on pin 1, DC (+30V nominal) modulated with channel 1 audio (-10dBu nominal) on pin 2, and channel 2 audio (-10dBu nominal) on pin 3

#### **Maximum Level:**

Pin 2 Outputs (DC with Channel 1 Audio): +9dBu (+23dBu on audio input)

Pin 3 Outputs (Channel 2 Audio): +14dBu (+28dBu on audio input)

#### **Connectors:**

**Audio Inputs:** 1, 25-pin, female, D-subminiature, 4-40 threads

**IFB Outputs:** 4, 3-pin, male, XLR-type

**AC Mains:** 3-blade, IEC 320 C14-type (mates with C13-type socket)

#### **AC Mains Requirement:**

100-230V, 50/60Hz, 0.7A maximum @ 100V, 0.4A maximum @ 230V

#### **Dimensions (Overall):**

19.00 inches wide (48.3cm)

1.72 inches high (4.4cm)

9.58 inches deep (24.3cm)

**Mounting:** one space in a standard 19-inch rack

**Weight:** 6.4 pounds (2.9kg)
